

# Duplication Tables

---

*Duplication tables are used to estimate how many copies of a title will provide specified levels of availability: .50 (minimal), .68 (moderate), or .95 (full). Unlike other duplication systems, this approach is based on objective data from your own collection. The underlying formula is a simple tool crib model from the operations research literature. The estimate is calculated from the annual circulation totals in your library for the title itself, if that is available; from the annual circulation of the last title published by an author; or from the title turnover for a format, genre or topic.*

## **Use Duplication Tables with existing titles and new purchases**

These Duplication Tables will help you decide how many additional copies you need for high-demand titles in the existing collection. You may also use the tables to determine the number of duplicates for new fiction titles and picture books as you select them. High-demand topics in nonfiction also repay routine initial review.

Applying the tables in this way helps you anticipate demand rather than waiting for reserves to accumulate before adding copies. It also identifies mid-list authors and topics that may benefit from moderate duplication. This will boost the perceived variety of your collection, and can result in higher overall circulation than more extensive duplication of a few best-sellers.

## **Estimates will change to meet demand**

The tables are sensitive to changes in demand, but the estimate is limited by the actual number of circulations in your

library's records for the title, author, or other factor that you investigate. If there is high unsatisfied demand, the existing records may not reflect total demand, and so the duplicate estimate may not be sufficient to meet the predicted level of availability. For this reason it is important to recalculate the estimates when a new title is issued by an author or after additional copies of an existing title have circulated for 6 months to a year.

Once demand is reflected accurately in the circulation record, the estimate will level out. The system is self-balancing in both directions; if demand for an author decreases, this reduces circulation totals and the duplication estimate will decrease.

## **Use annual circulation estimates**

You must use annual circulation estimates with the tables; the underlying calculations assume one year's worth of data. If you have less (or more) than a year of data, annualize the totals by finding a monthly average and then multiplying by 12.

## How to use the tables

- |   |   |
|---|---|
| <p><b>I. Estimate the annual circulation for the title.</b></p> <p><b>A. If you already own copies:</b><br/>Determine the annual number of circulations by adding together the most recent annual circulation of all copies of the title that you own. Use the raw total of the circulations, not the average per copy.</p> <p><b>OR</b></p> <p><b>B. If you do not already own copies:</b><br/>If you have other titles in the collection by the same author, determine the annual number of circulations for the most recent title in your collection by the author, as in “A” above. If the author writes in more than one genre, or publishes both fiction and nonfiction, you may also want to check the most recent title in the genre or format that most clearly matches the title at hand to take into account any variations in demand</p> <p><b>OR</b></p> <p>If the author is new to your collection, determine the title turnover for the format, genre, or topic. The title turnover is the average annual circulation of the <i>titles</i> (not copies). If title turnover cannot be calculated, you can use copy turnover, but doing so may underestimate the number of copies needed if the collection has a high ratio of copies to titles.</p> | <p><b>II. Use the Duplication Tables to find the number of copies you need:</b></p> <p><b>A. Decide which table to use.</b><br/>The tables are arranged by 1-week, 2-week, 3-week, and 4-week standard loan periods, then by the percentage of availability that you wish to achieve. Select the table that corresponds to the standard loan period for the title you are concerned with. Then choose 50% availability for minimal duplication, 68% availability for moderate duplication, or 95% availability for full duplication. You may also use the underlying formula to estimate 99% availability for an “always available” level of duplication.</p> <p><b>B. Look up the number of copies in the table.</b><br/>Locate the annual number of circulations you determined in Step 1 in the column labeled “Circs.” The number in the column to the right (“Copies”) is an estimate of the total number of copies you need for the availability level you have selected. If you already own copies of the title, subtract those from the copy estimate to determine the number of copies to add.</p> |
|---|---|

Separate tables show the number of copies needed for 50%, 68%, and 95% availability.

There are two pages for each availability level, covering titles with 1-300 and 301-600 circulations.

Tables are provided for 7, 14, 21, and 28 day loan periods

**Loan Period: 21 Days Availability: 68% Circulations: 1 - 300**

**Circ:** In your library's circulation records, find the number of circulations for A) all copies of the title you already own, or B) if you don't already own the title, all copies of the last title published by the author. If there are no author data, use the title turnover of the format, genre or topic of the title. Estimate the number of annual circulations in the last year from the data.

**Copies:** This column shows the number of copies you need to meet the specified availability level, including any copies you already own.

## Tips for Using the Tables

1. Over time, multiple copies of a title tend to have nearly the same number of circulations. If there are copies that have significantly lower circulation, they are probably missing. If they have been missing less than a year, convert their circulation to the average for the remaining titles and add that estimate to the total.
2. The tables require that the circulation estimate be annualized. If you have less than a year's worth of data for a title, convert the circulation to a full year by calculating a daily average and multiplying by 365. Keep in mind that the first few months of circulation are ordinarily the highest in the life of a title, and so estimates derived from just a few months of activity may be high. You need at least 4-6 months of data to be reasonably accurate. You can also use the technique of estimating annual circulation from a daily average if you have more than a year's worth of data, but beyond 18-24 months of circulation, the estimate may be too low to account for initial demand.
3. Fiction genre titles, such as mysteries and science fiction, tend to have an initial high circulation, but subside quickly once most avid followers of the genre have read the title. Be conservative about adding genre duplicates until you are familiar with the patterns for your own library. New titles in nonfiction should also be duplicated with caution until you have a sense of the underlying long-term demand.
4. Calculate the duplicates for multiple-branch libraries by determining the total number of copies needed for the system as a whole. Sum the annual circulation for all copies at all branches, and use that total to find the number of copies in the Duplication Tables. Allocate copies among branches by the share of total system circulation for the format, genre, or topic at each branch. This method favors larger branches, so it is wise to round up the estimate for smaller branches to the nearest full copy.
5. The tables may be used to estimate the number of copies of an older title to keep when you are weeding. Determine the most recent annual circulation for all copies of the title, and use that total to find the corresponding number of copies in the Duplication Tables. If you cannot determine the most recent annual circulation, use the average annual circulation over the life of the title. That will slightly overestimate the number of copies needed.

As you have already purchased the copies, this might be an instance when you apply a 99% availability rate, which you can calculate using the duplication formula in the Appendix. When you weed the extra copies, examine each one and discard those in the worst physical condition.
6. The tables provide estimates for titles with 1-600 annual circulations. If you have more than 600 annual circulations for a title, divide the total circulations into increments of 600 plus any remainder. Look up the copy estimates for 600 circulations and for the remainder. Multiply the estimate for 600 circulations by the number of increments of 600 that you have, and then add the estimate for the remainder. This will give you the total number of copies needed. This method works because at higher levels of circulation,

- the formula is linear. The number of circulations and duplicates increase directly, at essentially the same rate.
7. Many libraries establish a copy per title maximum beyond which they buy no duplicates, no matter how high the demand. With the use of such a maximum as an indicator of the outer boundary of a library's duplication effort, it is possible to construct a scaled duplication table for a specific library. Such a table provides an initial high level of duplication (95% or 68% availability) for titles that are mid-range in demand, and then gradually reduces the duplication level to that of 50% availability, terminating at a maximum of the library's choosing. If you are interested in pursuing such an approach, contact Roy Kenagy: (515) 419-3394, [rjkenagy@netins.net](mailto:rjkenagy@netins.net).
  8. The Duplication Tables are based on a formula from the operations research literature used to solve the "tool crib" problem: estimating the number of shared tools required in a workplace to ensure that all workers are supplied with tools as needed, but that the tools are not oversupplied. The model makes use of the Expectation of Life formula, which underlies many of the mathematical relationships in collections work. The Appendix sets out both formulas and provides worksheets and article citations to aid in understanding them.
  9. To make the tables easily accessible to libraries without requiring additional local research, I have applied several assumptions to the tool crib model. These assumptions, supported by empirical research by myself and others, are:
    - 1) the average recorded loan period of an item is roughly equal to the standard loan period for the item;
    - 2) loan periods follow the normal distribution;
    - 3) the standard deviation for the length of loan periods is around 10 days; and
    - 4) items with identical loan periods and similar circulation histories will follow similar demand patterns.

If a library prefers to research and implement the exact tool crib variables for their own collections, the key measures are the mean and standard deviation for the recorded length of loans in each of the collections they wish to model.
  10. I have introduced a constant of one copy to the tool crib model, again based on empirical experience. This front-loads the number of copies at initial levels of demand. The modification is a form of priming the breadth of the experienced collection, supporting variety at the shelf for browsing, and encouraging the circulation of mid-range authors and topics that are under-developed in conventional duplication practice concentrated on best sellers.
  11. The tables account for circulations resulting from browsing as well as known-item requests. However, if circulation interference has resulted in annual circulation totals that underrepresent the demand for a title, the estimated number of copies may still be low. As an author publishes subsequent titles, this will tend to correct itself as the estimate comes closer to the satisfaction level. The tables also function in reverse: as demand for an author or topic decreases, the number of estimated copies will decrease. The estimates are not static, and should be revisited whenever a new title is published.

**Loan Period: up to 7 Days**

**Availability: 50%**

**Circulations: 1 - 300**

# Appendix

## 1. The Expectation of Life formula

*For a stable population,*

$$\text{Average Life Expectancy} = \frac{\text{Population Size}}{\text{Entrants Per Time Unit}}$$

$$\text{Entrants Per Time Unit} = \frac{\text{Population Size}}{\text{Average Life Expectancy}}$$

$$\text{Population Size} = \text{Average Life Expectancy} \times \text{Entrants Per Time Unit}$$

---

*For the insurance industry,*

$$\text{Average Life Expectancy} = \frac{\text{Population Size}}{\text{Annual births}}$$

$$\text{Annual Births & Deaths} = \frac{\text{Population Size}}{\text{Average Life Expectancy}}$$

$$\text{Population Size} = \text{Average Life Expectancy} \times \text{Annual Births}$$

---

*For library applications, the terms in the equations might refer to:*

Average Life Expectancy	Average: length of loan discard age
Entrants Per Time Unit	Average number of items per time unit: acquired loaned returned put on display discarded
Population size	Average number of items: owned on loan on display waiting to be reshelfed

### **Some Library Examples:**

$$\text{Average length of loan} = \frac{\text{Average number of items on loan}}{\text{Average number of items loaned per time unit}}$$

$$\text{Average number of items loaned per time unit} = \frac{\text{Average number of items on loan}}{\text{Average length of loan}}$$

$$\text{Average number of items on loan} = \text{Average length of loan} \times \text{Average number of items loaned per time unit}$$

### **Library Applications**

- Average:**
- ▶ **Items on loan** for a class of materials
  - ▶ **Number of duplicates** to maintain specified levels of availability
  - ▶ **Discard age** in a no-growth collection
  - ▶ **Days per loan** for a class of materials
  - ▶ Daily and annual **circulation** for a class of materials
  - ▶ **Circulation** for a permanent browsing display
  - ▶ **Random availability** for a class of materials
  - ▶ **Turnaround Time**
    - ▶ Interlibrary Loan
    - ▶ Reserve Requests
    - ▶ Acquisitions
    - ▶ Cataloging
    - ▶ Shelving

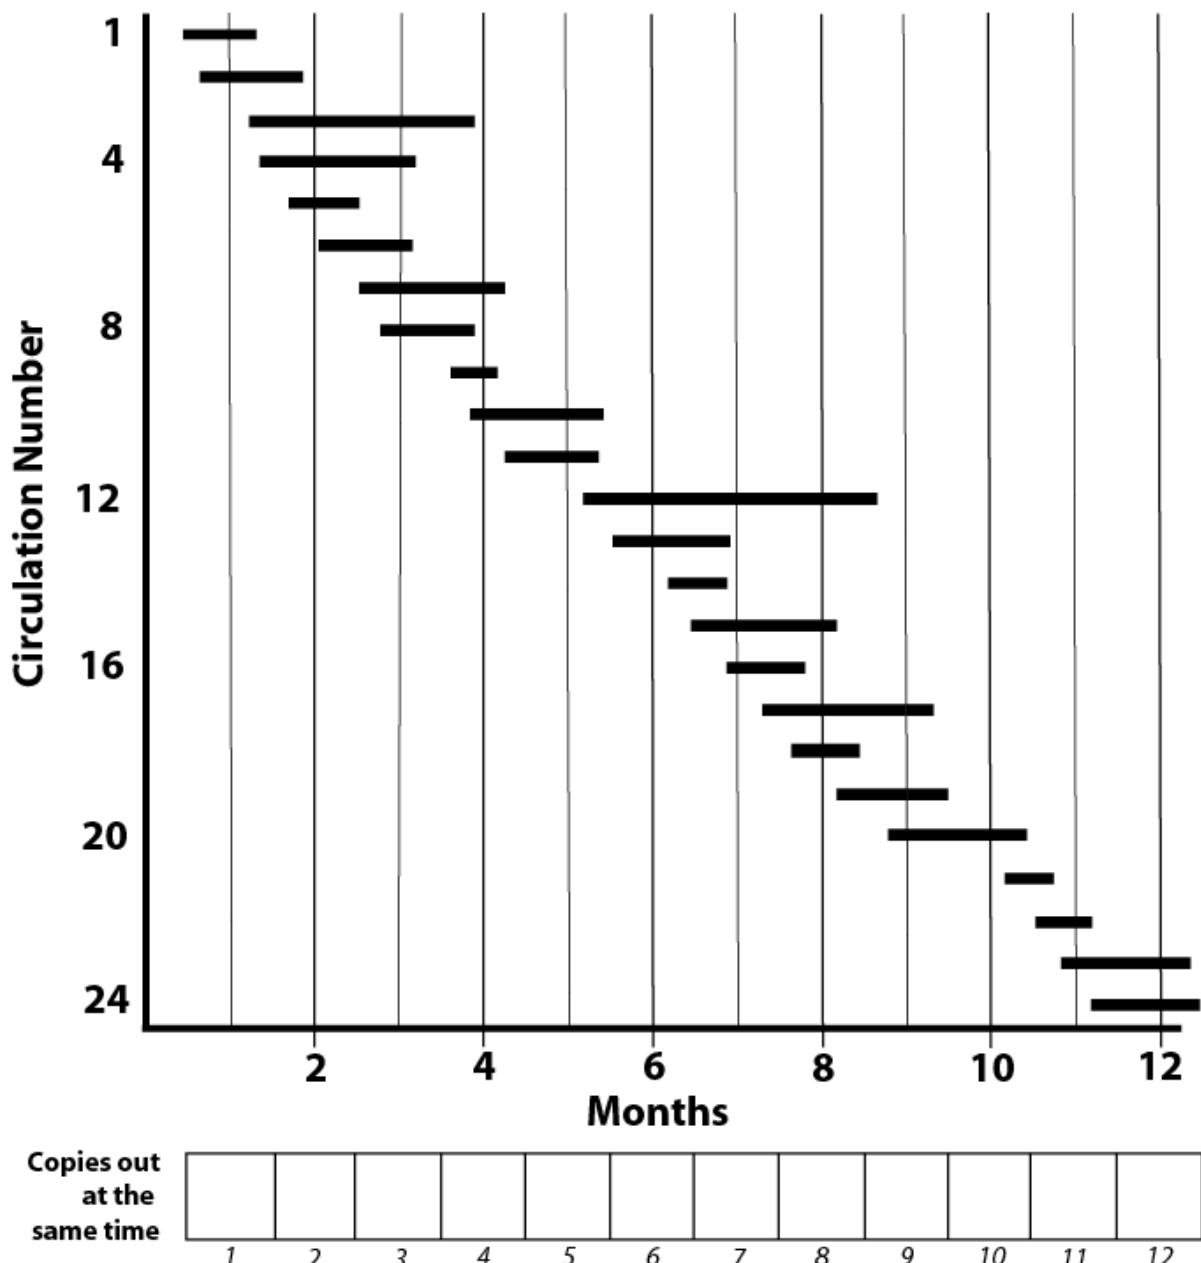

---

### **Based on:**

Verhoeven, Stanley M. "The Expectation of Life Formula Applied to Collection Management." *Collection Management* 8, no. 2 (Summer 1986): 11-29.

## 2. The Tool Crib formula

**Typical Circulation History**  
**Four week loan period, 24 annual circulations**

$$\text{Average Number of Loans per month} = \boxed{\quad}$$

To find the average number of items out using the Expectation of Life formula:

$$\text{Average number of items on loan} = \frac{\text{Average length of loan}}{\text{X}} \times \text{Average number of items loaned per time unit}$$

$$\text{Average number of items on loan} = 1 \text{ month} \times 2 = 2$$

Or, using days rather than months as the time unit:

$$\text{Average number of loans per day} = \boxed{\quad}$$

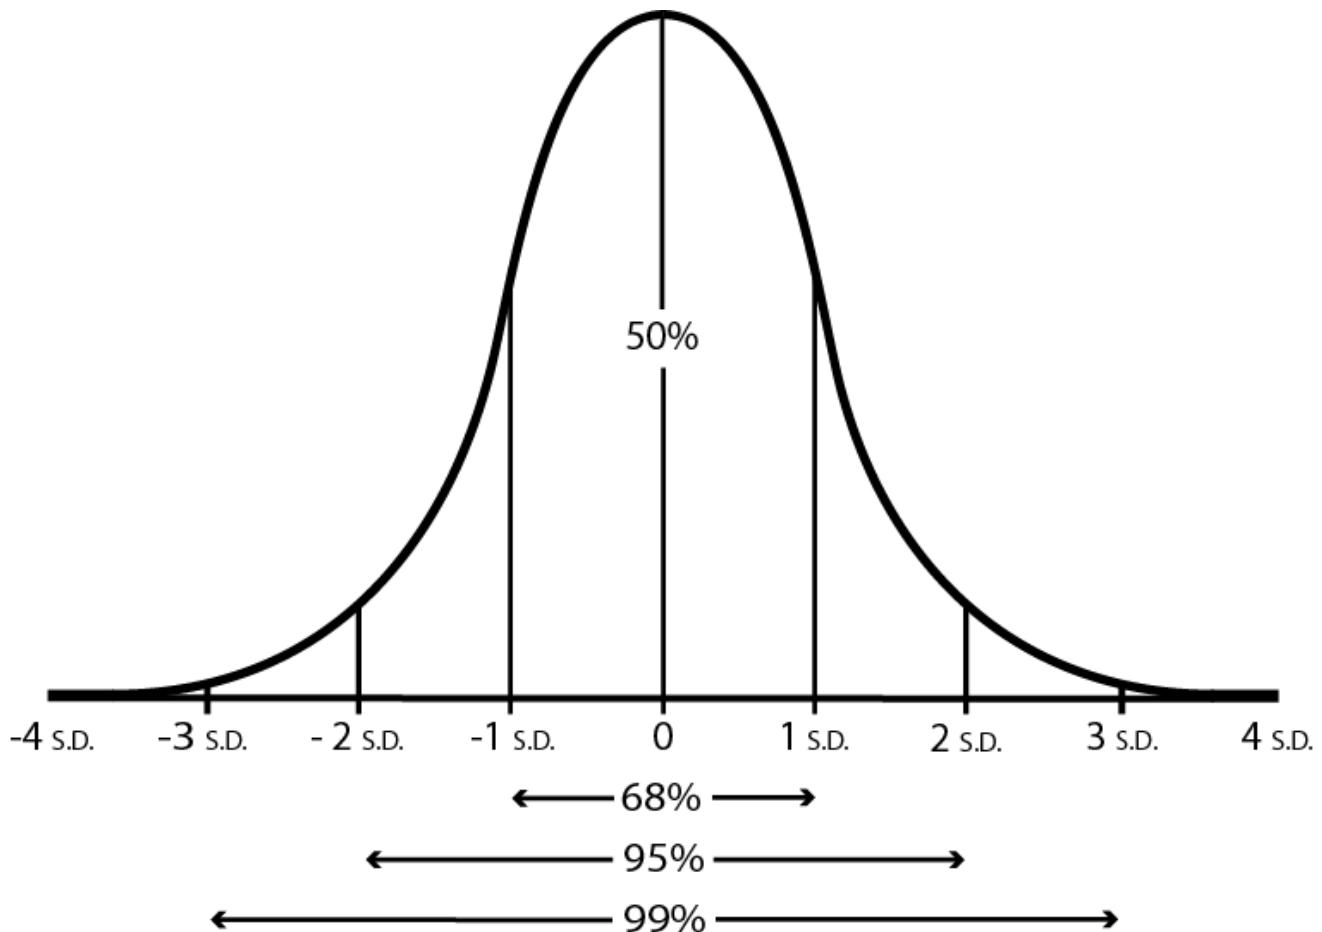

$$\text{Average number of items on loan} = 28 \text{ days} \times .066 = 1.8$$

The Expectation of Life formula yields the average number of items on loan, but looking at the circulation history we can see that often more items are on loan than the average. In fact, if we limit the number of copies to the average items on loan, we will anticipate only 50% of the demand.

The Tool Crib formula solves this dilemma by increasing the number of days in the formula to anticipate the maximum number of days at or below which an item will be out for specific levels of probability. The Standard Deviation (S.D.) is the usual measure of dispersion for a distribution, and for a normal distribution we can anticipate that a given percentage of instances will be at or below 1, 2, or 3 standard deviations from the mean. Specifically:

<i>For the number of loans equal to:</i>	<i>The loan lengths will be at or below:</i>
50%	Mean (average)
68%	Mean + 1 S.D.
95%	Mean + 2 S.D.
99%	Mean + 3 S.D.

## The Normal Curve

Empirical observation indicates that the S.D. (Standard Deviation) for the typical length of loan in a public library is in the range of 10 days. Empirical observation also indicates that the mean length of loan is close to the standard loan period of a class of items. The following table is based on these observations plus the assumption that the number of days on loan are normally distributed.

### Maximum expected days on loan by percentage of total loans:

Standard loan period =	1 week	2 weeks	3 weeks	4 weeks
Percentage of total loans at or below the expected days on loan	50%	7	14	21
	68%	17	24	31
	95%	27	34	41
	99%	37	47	51

### 3. The Duplication Formula

The complete duplication formula is derived from the tool crib model, which in turn is derived from the Expectation of Life formula. I have added a base constant (1) to the original tool crib model to promote variety at the shelf, encourage browsing, and allow for declining use over time.

$$\text{Number of copies} = 1 + \left( \text{Days in loan period} \times \frac{\text{Number of circulations}}{\text{Days in circulation life}} \right)$$

<b>Number of copies</b>	Total copies recommended for the collection (including current copies, if any).
<b>Days in loan period</b>	To satisfy 50% of the demand, use the number of days in the formal loan period for the material type (example: 2 week adult fiction loan period = 14 days). To satisfy increasing percentages of demand, use the table below.
<b>Number of circulations</b>	Total circulation count for all copies of the measured title in a known Circulation Life period.
<b>Days in circulation life</b>	Days the copies of the measured title have been active for circulation; days in sample period during which the number of circulations are totaled. The Duplication Tables use one year (365 days).

#### Demand Estimates

To satisfy **50%** of demand: use average length of loan period (as in formula)

**68%** of demand: add **10 days** to the Days in Loan Period

**95%** of demand: add **20 days**

**99%** of demand: add **30 days**
